Classification

Boston University CS 506 - Lance Galletti

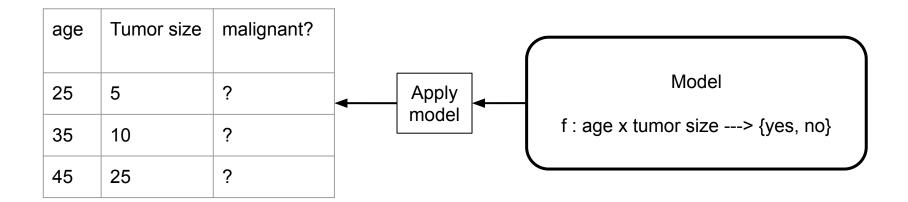

What is Classification?

- Given a training set where data is labeled with a special attribute called a class (a discrete value)
- We want to find a model for the class attribute as a function of the values of the other attributes
- Goal: use this model on unlabeled data to assign a class as accurately as possible

Example

Example

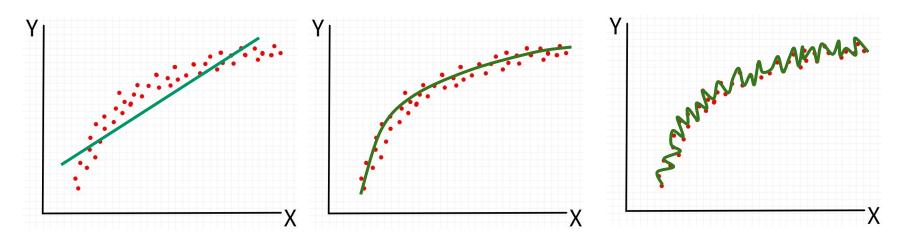

Classification Tasks

- Predicting tumor cells as benign or malignant
- Classifying images
- Classifying credit card transactions as being legitimate or fraudulent
- Many more

Classification Techniques

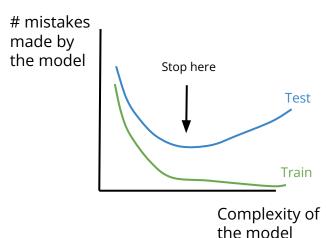

- Instance-Based Classifiers
- Decision Trees
- Naive Bayes
- Support Vector Machines
- Neural Networks

Underfitting VS Overfitting

Model Evaluation (simply)

- Evaluating a model on the data it was trained on is cheating - can just memorize.
- Distinction between data used for training and data left out used for testing / evaluation.

Instance-Based Classifiers

- Use the stored training records to predict the class label of unseen cases
- Rote-learners:
 - Perform classification only if the attributes of the unseen record exactly match a record in our training set
- Nearest Neighbor:
 - Use the k closest records to perform classification

Instance-Based Classifiers

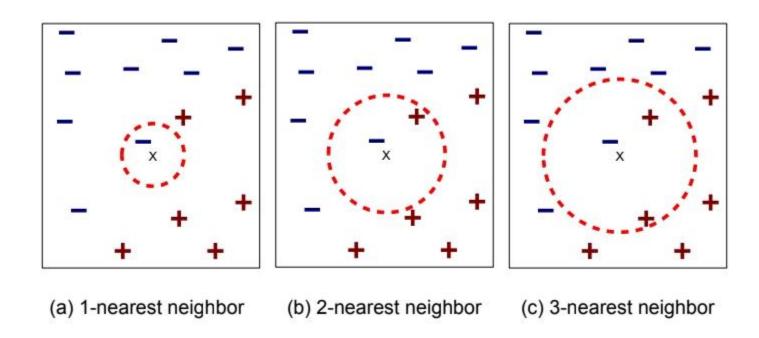

age	Tumor size	malignant?				
20	10	no		200	Tumor size	malignant?
30	15	yes	*	age	Tulliol Size	mangnant!
40	20	no		25	5	?
50	25	yes			,	

Requires:

- Training set
- Distance function
- Value for k

How to classify an unseen record:

- 1. Compute distance of unseen record to all training records
- 2. Identify the k nearest neighbors
- 3. Aggregate the labels of these k neighbors to predict the unseen record class (ex: majority rule)

Aggregation methods:

- Majority rule
- Weighted majority based on distance ($w = 1/d^2$)

Scaling issues:

- Attributes should be scaled to prevent distance measures from being dominated by one attribute. Example:
 - Height: 1m -> 2m
 - o Income: 10k -> 1million

Aggregation methods:

- Majority rule
- Weighted majority based on distance ($w = 1/d^2$)

Scaling issues:

 Attributes should be scaled to prevent distance measures from being dominated by one attribute. Example:

height

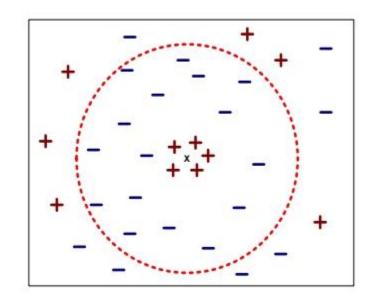

Height: 1m -> 2m

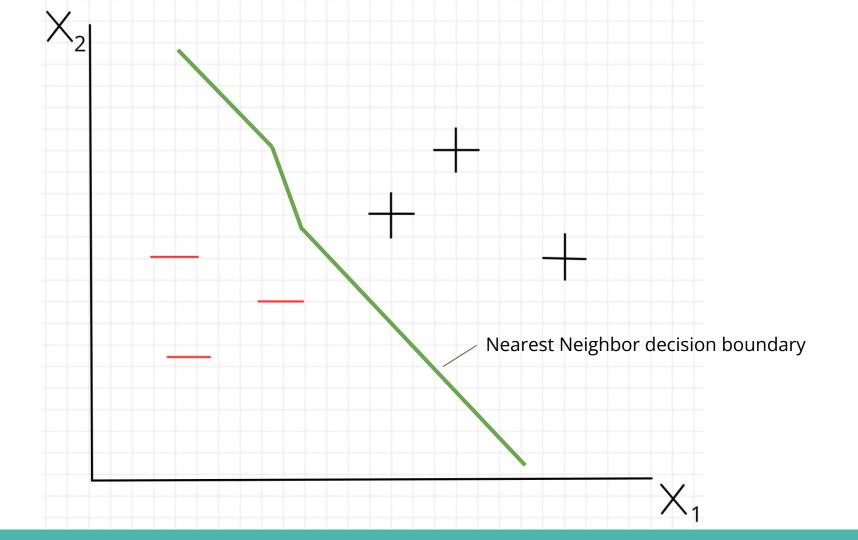

o Income: 10k -> 1million

Choosing the value of k:

- If k is too small -> sensitive to noise points + overfitting (doesn't generalize well)
- If k is too big -> neighborhood may include points from other classes

Pros:

- Simple to understand why a given unseen record was given a particular class
- Adapts to new attributes

Cons:

- Expensive to classify new points
- KNN can be problematic in high dimensions (curse of dimensionality)
